

TECHNICAL PRESENTATION

Decision Support Systems (DSS)

Definition and Need of DSS:- A Decision Support System (DSS) is a computer-based information system that helps managers and decision-makers analyze data and make better decisions.

2. Components of DSS:- a) Data Component , b) Model Component , c) User Interface (UI)

3. Types of DSS :- a) Data-Driven DSS, b) Model-Driven DSS,
c) Knowledge-Driven DSS d) Document-Driven DSS

A Decision Support System is a computer-based system that helps managers and organizations make better decisions using data, models, and analytical tools. DSS is needed because businesses face complex problems and require quick, accurate decisions. A DSS consists of three main components: Data, which provides information; Models, which analyze the data; and the User Interface, which allows users to interact with the system.

There are several types of DSS, including Data-Driven, Model-Driven, Knowledge-Driven, Document-Driven, and Communication-Driven systems. DSS is widely used in banking for loan approval, fraud detection, and risk assessment. In healthcare, it helps doctors diagnose diseases, recommend treatments, and manage hospital resources. The main advantages of DSS are improved decision quality, faster decision-making, and reduced risks. However, DSS also has limitations such as high cost, dependence on accurate data, and the inability to replace human judgment.

There are many advantages of DSS. It improves decision quality, increases efficiency, reduces uncertainty, saves time, and supports strategic planning. It also helps organizations respond quickly to changing business conditions. To conclude, Decision Support Systems are essential tools that help organizations make informed, efficient, and effective decisions. They transform raw data into valuable information and play a vital role in modern business and management.
